

Description:

- In the experiment you will be given the code differences between two releases (old and new) of a selected source or header file
 - o Each line begins with the symbol "+" means it has been added (new release)
 - o Each line begins with the symbol "-" means it has been removed (old release)
 - o Each line does not start with "+" or "-" means it remains the same in the both releases (common)
- The UML class diagram of the old release is also provided next to the code changes
- For each case you have to decide if the code changes cause a design change or not (i.e. change the given UML diagram). Design change means:
 - o Add or delete a class
 - o Add or delete method
 - o Add or delete inheritance relationship
 - o Add or delete association relationship
 - o Add or delete aggregation relationship
 - o Add or delete dependency relationship

Relationships

- Association from class A to class B, if A has a data member of type B.
- Aggregation between class A and class B, if A has a container *data member* that contains objects of B.
- Dependency from class A to class B, if A has a method contains a local variable of type B.
- **Key:**

Important notes

- *Ignore multiplicity of relationships.* For example if there exist a dependency between two classes in the given UML diagram and the code change shows that the same dependency has been added, then it is not a design change.
- *Ignore method overloading.* Consider only unique method names.

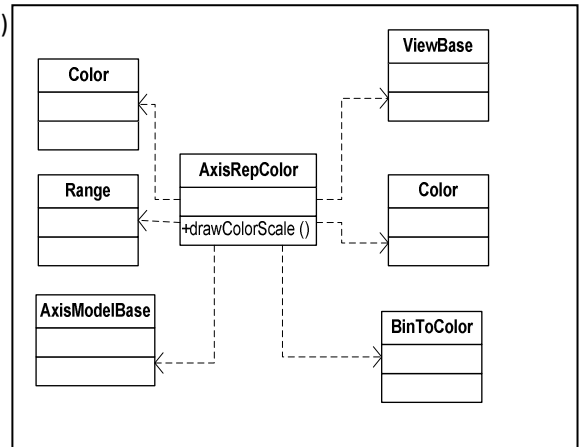

- **Case 1:**

```
